Precise Vertical Reference Surface Representation and Precise Transformation of Classical Networks to ETRS89 / ITRS General Concepts and Realisation of Databases for **GIS, GNSS and Navigation Applications in and outside Europe**

Prof. Dr.-Ing. Reiner Jäger, Dipl.-Ing. (FH) Simone Kälber, Dipl.-Ing. (FH) Sascha Schneid and Dipl.-Ing. (FH) Stephan Seiler

As concerns the georeferencing of position data in modern data bases, the availability of GNSS (GPS / GLONASS / GALILEO) related code- and phase-measurement DGNSS-correction data, which are provided in different ways by different GNSS positioning services (SAPOS, ascos, SWIPOS, SWEPOS etc.) in and outside Europe leads to the replacement of the classical geodetic reference systems by GNSS-consistent ITRS-based reference systems. So the transformation of the old plan position data (N,E)_{class} related to the classical reference systems to the ITRS/ETRS89 datum (N,E)_{ITRS} becomes urgently necessary all over Europe (1) and the world respectively. A sophisticated and general solution of this transformation problem has to include a respective data base concept for the provision of the corresponding transformation parameters for GIS, GNSS and Navigation purposes. This is provided by the CoPaG-Concept. Further the capacity of a one-cm-positioning by GNSS services, such as e.g. SAPOS® and ascos® in Germany, is also appropriate for a GNSS related heighting. The GNSS-based

determination of sea-level (orthometric, normal) heights H requires however the transformation of the ellipsoidal GNSS heights $h_{\pi\pis}$ to the respective physically defined height reference surface (HRS). A general concept for the evaluation of height reference surfaces (HRS)on the national and also on European level (E_HRS) is provided by DFHRS. Both the DFHRS and the CoPaG/DFLBF database standard are broadly accepted by the GNSS indurstry (5).

The CoPaG concept is dealing with the precise and continuous transformation of plan positions $(N,E)_{class}$ to the ITRS/ETRS89 datum $(N,E)_{TRS}$. From the theoretical point of view a respective transformation can not renounce completely on height information (C1). The so-called COPAG (<u>CO</u>ntinuously <u>PA</u>tched <u>G</u>eoferencing)

are due to the occurrence and the mathematical treatment of so-called 'weak-forms'(C2, C3 left). These are long-waved deflections of the network shape of the classical networks, reaching a range of several meters in the nation-widescale, e.g. for the size of Germany (C3, left side). This requires the partition of the total network area into a set of different "patches" (C3, right). The introduction of continuity
